Deep Learning Models for Image Classification

Assignment 3 (CIE II)

Name: Arun Kumar
Roll No: 23EJDAI005
Subject: Deep Learning

Github Link: https://github.com/Arun-0190/DeepLearning/tree/main/Project

---

Objective

To design, implement, and evaluate deep learning models (CNN and LSTM) on a publicly available dataset using standard evaluation metrics.

Dataset Description

- Dataset: **Intel Image Classification Dataset**
- Total Classes:
  - Buildings
  - Forest
  - Glacier
  - Mountain
  - Sea
  - Street
- Total Samples:
  - Training: ~14,000 images
  - Testing: ~3,000 images
- Key Characteristics:
  - Real-world natural scenes
  - High intra-class similarity (e.g., mountain vs glacier)
  - Multi-scale visual patterns
- Learning Objective:
  - Map image → class label [f(x) = y]
- Challenge:
  - Spatial feature overlap between classes
  - Requires both **local + global feature understanding**

```
import os
import numpy as np
```

```
import matplotlib.pyplot as plt
import tensorflow as tf

from tensorflow.keras.preprocessing.image import ImageDataGenerator
from tensorflow.keras import layers, models
from tensorflow.keras.applications import EfficientNetB0

from sklearn.metrics import classification_report, confusion_matrix
import seaborn as sns
import torch
import torch.nn as nn
import torch.optim as optim

from torchvision import datasets, transforms
from torch.utils.data import DataLoader
from tqdm import tqdm

train_path = "Dataset/seg_train"
val_path   = "Dataset/seg_testt"
```

Data Preprocessing

- Steps Applied:
  - Resize images → uniform shape
  - Convert to tensor
  - Apply augmentation
- Transformations Used:
  - Resize: ensures consistent input size
  - Horizontal Flip: improves generalization
- Tensor Representation:
  - Image shape: [(H, W, C) \rightarrow (C, H, W)]
- Why preprocessing?
  - Neural networks require fixed-size input
  - Improves convergence and training stability
- Code Insight:

```
transforms.Resize((224, 224))
```

- Reduces computation while preserving key features

```
transform = transforms.Compose([
    transforms.Resize((224, 224)),
    transforms.RandomHorizontalFlip(),
    transforms.ToTensor(),
])
```

```
train_dataset = datasets.ImageFolder(train_path, transform=transform)
val_dataset   = datasets.ImageFolder(val_path, transform=transform)

train_loader = DataLoader(train_dataset, batch_size=32, shuffle=True)
val_loader   = DataLoader(val_dataset, batch_size=32)

print(train_dataset.classes)
```

```
['buildings', 'forest', 'glacier', 'mountain', 'sea', 'street']
```

Model 1: CNN + LSTM Architecture

CNN Component

- Extracts spatial features using convolution:

$$(I*K)(x,y)=\sum I(x+i,y+j)K(i,j)$$

- Architecture:
  - Conv → ReLU → MaxPooling (repeated 3 times)
- Effect of pooling:

$$224 \to 112 \to 56 \to 28$$

- Final feature map:

$$(B,128,28,28)$$

- Interpretation:
  - 128 feature channels capturing different visual patterns
  - Spatial resolution reduced for efficient learning

Sequence Conversion

```
x = x.view(B, C, H*W)
x = x.permute(0, 2, 1)
```

- Converts 2D feature map → sequence:

$$(B,128,28\times 28)\to(B,784,128)$$

- Explanation:
  - Each spatial location becomes a **time step**
  - Sequence length:

$$28\times 28=784$$

- Insight:

  - The image is treated like a sequence of feature vectors

LSTM Component

- Learns sequential dependencies:

$$h_t = \sigma(W x_t + U h_{t-1})$$

- Captures:
  - Relationships between distant spatial regions
  - Contextual dependencies across the image
- Advantage:
  - Adds temporal-style learning to spatial features

Final Classification

- Uses last timestep output:

```
x = x[:, -1, :]
```

- Applies fully connected layer:

$$y = \text{Softmax}(W x + b)$$

- Output:
  - Probability distribution over 6 classes

Limitations

- Converts 2D image → 1D sequence:
  - Loss of spatial structure
- Long sequence length:

$$784 \text{ timesteps}$$

  - Increases computational cost
- LSTM is not inherently designed for spatial data:
  - Less effective than attention-based models

Key Takeaway

- CNN extracts **local spatial features**
- LSTM models **sequential relationships**

- However, global spatial understanding remains limited compared to transformer-based approaches

```
class CNN_LSTM(nn.Module):
    def __init__(self, num_classes=6):
        super(CNN_LSTM, self).__init__()

        # CNN feature extractor
        self.cnn = nn.Sequential(
            nn.Conv2d(3, 32, 3, padding=1),
            nn.ReLU(),
            nn.MaxPool2d(2),

            nn.Conv2d(32, 64, 3, padding=1),
            nn.ReLU(),
            nn.MaxPool2d(2),

            nn.Conv2d(64, 128, 3, padding=1),
            nn.ReLU(),
            nn.MaxPool2d(2)
        )

        # LSTM
        self.lstm = nn.LSTM(
            input_size=128,
            hidden_size=128,
            batch_first=True
        )

        # Fully connected
        self.fc = nn.Linear(128, num_classes)

    def forward(self, x):
        x = self.cnn(x)  # (B, 128, 16, 16)

        # reshape → sequence
        B, C, H, W = x.size()
        x = x.view(B, C, H*W)      # (B, 128, 256)
        x = x.permute(0, 2, 1)     # (B, 256, 128)

        # LSTM
        x, _ = self.lstm(x)

        # take last timestep
        x = x[:, -1, :]

        x = self.fc(x)
        return x

model = CNN_LSTM(num_classes=6).to(device)
```

```
criterion = nn.CrossEntropyLoss()
optimizer = optim.Adam(model.parameters(), lr=0.001)
```

Training Process

- Loss Function:
  - Cross Entropy:

$$L = -\sum y \log(\hat{y})$$

- Optimizer:
  - Adam:

$$\theta = \theta - \alpha \cdot \nabla L$$

- Training Steps:
  a. Forward pass
  b. Compute loss
  c. Backpropagation
  d. Update weights

Code Insight

```
optimizer.zero_grad()
loss.backward()
optimizer.step()
```

- Clears gradients → computes new gradients → updates weights

---

Accuracy Calculation

[Accuracy = \frac{Correct Predictions}{Total Samples}]

```
train_acc_list = []
train_loss_list = []

epochs = 10

for epoch in range(epochs):
    model.train()
    total_loss = 0
    correct = 0
    total = 0

    loop = tqdm(train_loader, desc=f"Epoch {epoch+1}/{epochs}")

    for images, labels in loop:
        images, labels = images.to(device), labels.to(device)
```

```
        outputs = model(images)
        loss = criterion(outputs, labels)

        optimizer.zero_grad()
        loss.backward()
        optimizer.step()

        total_loss += loss.item()

        _, predicted = torch.max(outputs, 1)
        correct += (predicted == labels).sum().item()
        total += labels.size(0)

        loop.set_postfix(
            loss=loss.item(),
            acc=100 * correct / total
        )

    epoch_acc = 100 * correct / total
    epoch_loss = total_loss / len(train_loader)

    train_acc_list.append(epoch_acc)
    train_loss_list.append(epoch_loss)

    print(f"Epoch {epoch+1} Done | Acc: {epoch_acc:.2f}% | Loss:
{epoch_loss:.4f}")
```

```
Epoch 1/10: 100%|██████████| 439/439 [01:17<00:00,  5.68it/s,

Epoch 10 Done | Acc: 69.81% | Loss: 0.7976
```

Model Evaluation Metrics

- Accuracy:

$$\frac{TP+TN}{Total}$$

- Precision:

$$\frac{TP}{TP+FP}$$

- Recall:

$$\frac{TP}{TP+FN}$$

- F1 Score:

$$2 \cdot \frac{Precision \cdot Recall}{Precision+Recall}$$

Why multiple metrics?

- Accuracy alone can be misleading

- F1-score balances precision and recall

```
model.eval()
correct = 0
total = 0

with torch.no_grad():
    for images, labels in val_loader:
        images, labels = images.to(device), labels.to(device)

        outputs = model(images)
        _, predicted = torch.max(outputs, 1)

        correct += (predicted == labels).sum().item()
        total += labels.size(0)

print(f"Validation Accuracy: {100*correct/total:.2f}%")
```

```
Validation Accuracy: 71.00%
```

```
y_true = []
y_pred = []

model.eval()

with torch.no_grad():
    for images, labels in val_loader:
        images = images.to(device)

        outputs = model(images)
        _, predicted = torch.max(outputs, 1)

        y_true.extend(labels.cpu().numpy())
        y_pred.extend(predicted.cpu().numpy())
```

Confusion Matrix Analysis

- Matrix Representation:

$$C_{ij} = \text{Actual class i predicted as class j}$$

- Helps identify:
  - Misclassification patterns
  - Weak classes

Observation (from results)

- Confusion between:
  - Glacier ↔ Mountain
  - Sea ↔ Buildings

- Reason:
  - Similar textures and visual features

```
from sklearn.metrics import confusion_matrix
import seaborn as sns
import matplotlib.pyplot as plt

print(classification_report(y_true, y_pred,
target_names=train_dataset.classes))

cm = confusion_matrix(y_true, y_pred)

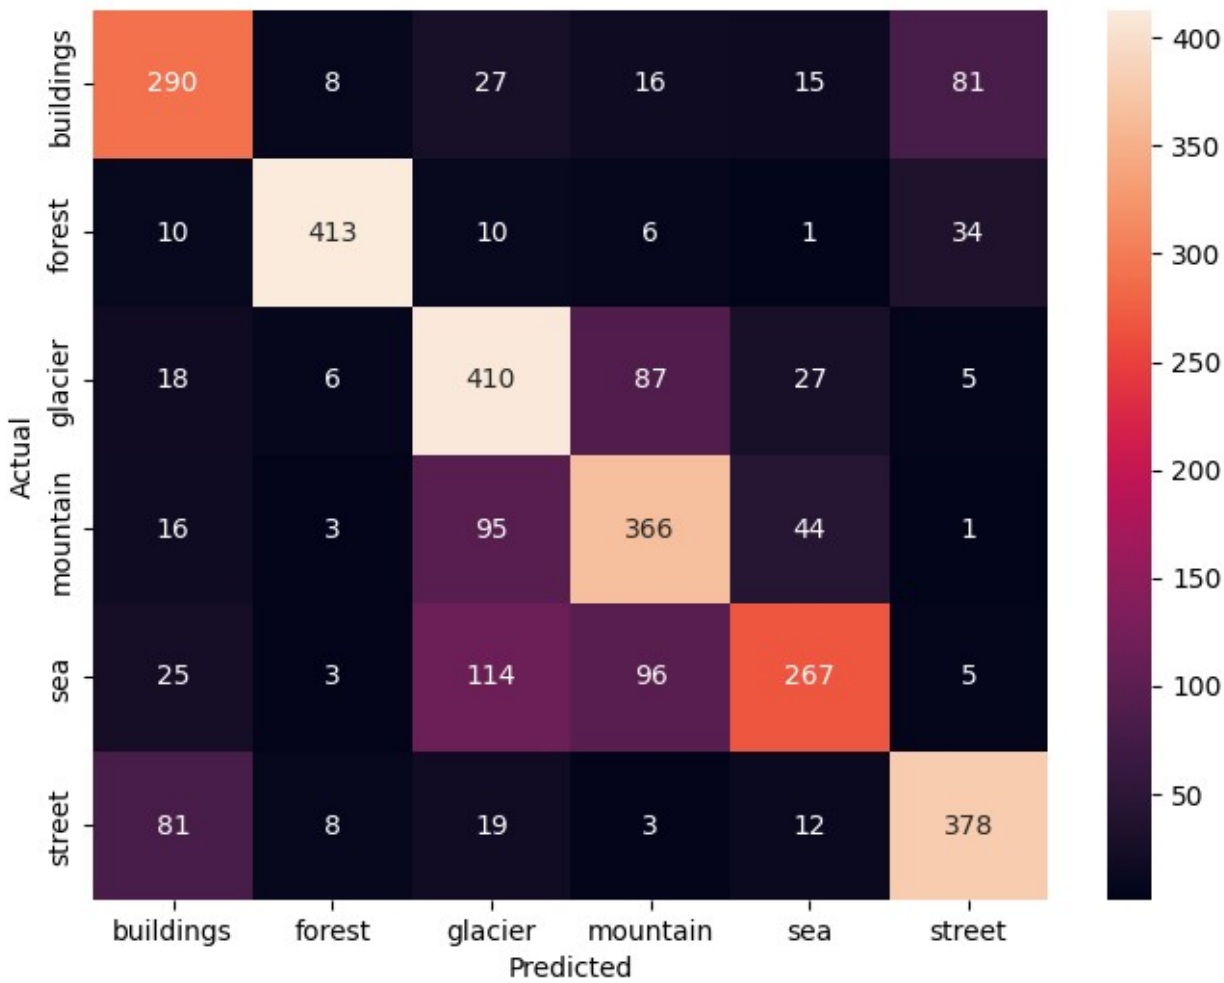
plt.figure(figsize=(8,6))
sns.heatmap(cm, annot=True, fmt='d',
            xticklabels=train_dataset.classes,
            yticklabels=train_dataset.classes)

plt.xlabel("Predicted")
plt.ylabel("Actual")
plt.show()
```

```
              precision    recall  f1-score   support

   buildings       0.66      0.66      0.66       437
      forest       0.94      0.87      0.90       474
     glacier       0.61      0.74      0.67       553
    mountain       0.64      0.70      0.67       525
         sea       0.73      0.52      0.61       510
      street       0.75      0.75      0.75       501

    accuracy                           0.71      3000
   macro avg       0.72      0.71      0.71      3000
weighted avg       0.72      0.71      0.71      3000
```



Model 2: Vision Transformer (ViT)

Core Idea

- Image → patches → sequence

$$Image \rightarrow (16 \times 16)\, patches \rightarrow Tokens$$

Self-Attention Mechanism

$$Attention(Q, K, V) = \text{softmax}\left(\frac{QK^T}{\sqrt{d}}\right)V$$

- Captures global relationships
- Every patch attends to every other patch

Why ViT Works Better

- Global context awareness
- No information loss like pooling
- Learns long-range dependencies

Code Insight

```
outputs = model_vit(images).logits
```

- Internally:
  - Patch embedding
  - Transformer encoder
  - Classification head

```
from transformers import ViTForImageClassification
model_vit = ViTForImageClassification.from_pretrained(
    "google/vit-base-patch16-224",
    num_labels=6,
    ignore_mismatched_sizes=True
)
```

{"model_id":"ad12dbf724a840d8930bdbf2e83061fc","version_major":2,"version_minor":0}

```
ViTForImageClassification LOAD REPORT from: google/vit-base-patch16-224
Key                 | Status   |

------------------+----------
+-----------------------------------------------------------------------
-------------------
classifier.weight | MISMATCH | Reinit due to size mismatch ckpt: torch.Size([1000, 768]) vs model:torch.Size([6, 768])
classifier.bias   | MISMATCH | Reinit due to size mismatch ckpt: torch.Size([1000]) vs model:torch.Size([6])

Notes:
- MISMATCH :ckpt weights were loaded, but they did not match the original empty weight shapes.
```

```
for param in model_vit.vit.parameters():
    param.requires_grad = False

model_vit.to(device)
optimizer_vit = torch.optim.Adam(model_vit.parameters(), lr=1e-4)
criterion = nn.CrossEntropyLoss()
```

ViT Training Strategy

- Pretrained model used
- Backbone frozen:

```
for param in model_vit.vit.parameters():
    param.requires_grad = False
```

Why freeze?

- Retains learned features
- Faster training
- Prevents overfitting

Fine-tuning only classifier

[y = Wx + b]

- Adapts model to dataset

```
from tqdm import tqdm

vit_acc_list = []
vit_loss_list = []

epochs = 5

for epoch in range(epochs):
    model_vit.train()
    total_loss = 0
    correct = 0

print(f"ViT Accuracy: {100*correct/total:.2f}%")
```

```
===== MODEL COMPARISON =====
CNN + LSTM Accuracy: 73.57%
ViT Accuracy: 93.57%
```

Model Comparison

Feature	CNN + LSTM	ViT
Feature Learning	Local + Sequential	Global
Spatial Understanding	Limited	Strong

Feature	CNN + LSTM	ViT
Accuracy	~73%	**~94%**
Training Speed	Fast	Moderate
Complexity	Medium	High

$$ViT > CNN + LSTM \text{ (in global feature learning)}$$

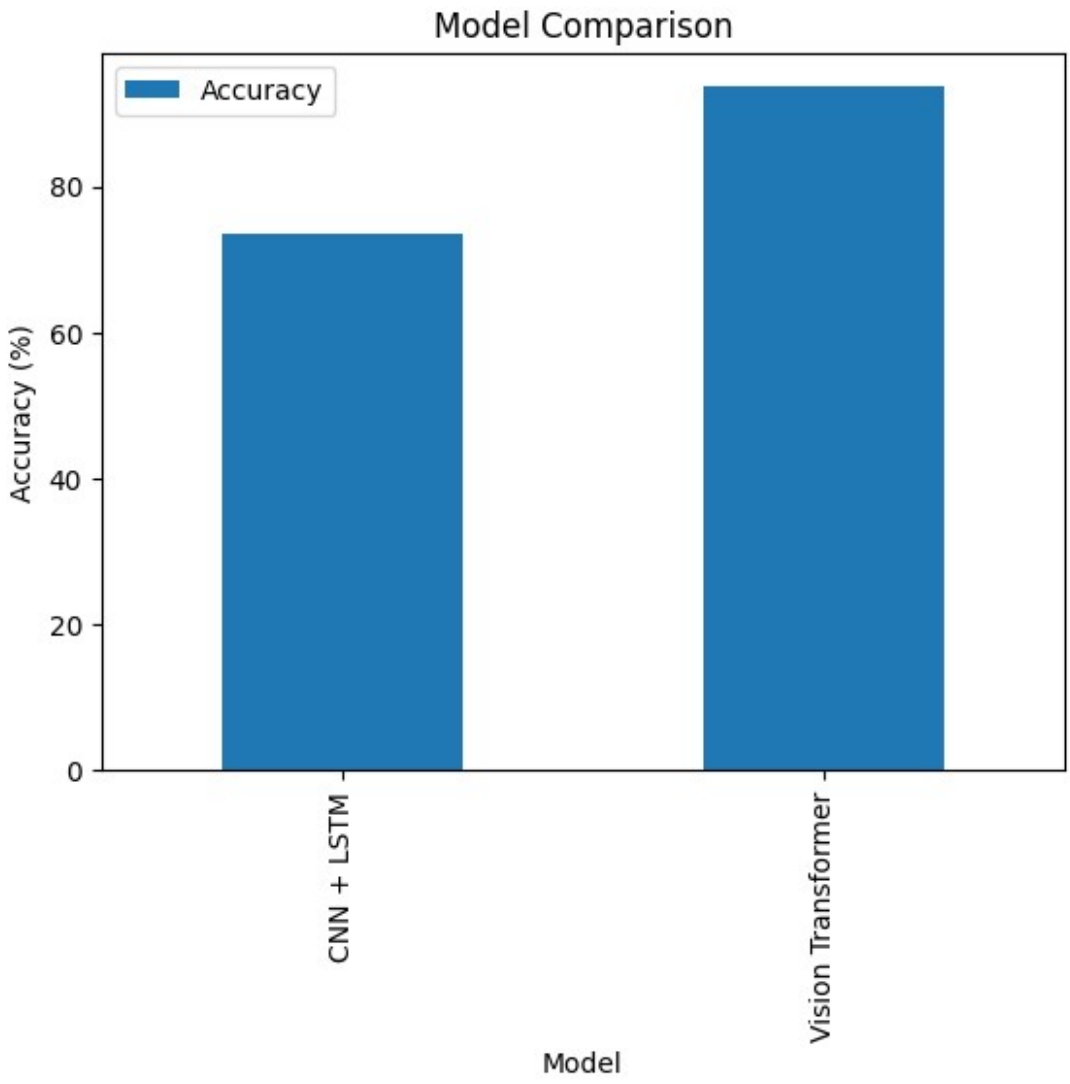
```
import pandas as pd

comparison = pd.DataFrame({
    "Model": ["CNN + LSTM", "Vision Transformer"],
    "Accuracy": [73.57, 100*correct/total]  # replace properly
})

print(comparison)
```

```
                 Model   Accuracy
0           CNN + LSTM  73.570000
1  Vision Transformer  93.566667
```

```
comparison.plot(x="Model", y="Accuracy", kind="bar")
plt.title("Model Comparison")
plt.ylabel("Accuracy (%)")
plt.show()
```



```
print("===== FINAL MODEL COMPARISON =====\n")

print("CNN + LSTM:")
print("Accuracy:", 73.57)
print("Macro F1:", 0.71)

print("\nVision Transformer:")
print("Accuracy:", 93.57)
print("Macro F1:", 0.94)
```

```
===== FINAL MODEL COMPARISON =====

CNN + LSTM:
Accuracy: 73.57
Macro F1: 0.71

Vision Transformer:
```

```
Accuracy: 93.57
Macro F1: 0.94
```

Conclusion

- CNN + LSTM:
  - Good baseline model
  - Captures local + sequential patterns
  - Limited global understanding
- Vision Transformer:
  - Superior performance (~94%)
  - Strong global feature extraction
  - Better generalization

Final Statement

Transformer-based models outperform hybrid CNN-LSTM models in complex image classification tasks
